INVESTIGATION OF PERFORMANCE OF TURBOJET ENGINE

WITH CONSTANT- AND VARIABLE-AREA

EXHAUST NOZZIJAS

By Lewis E. Wallner

#### SUMMARY

The performance of a turbojet engine with constant- and variable-area exhaust nozzles has been investigated in the NACA Cleveland altitude wind tunnel. The investigation was made at simulated altitudes from 5000 to 45,000 feet and simulated flight Mach numbers from 0.12 to 0.94.

The efficiency of the variable-area exhaust nozzle was from 1.5 to 8 percent lower than the efficiency of the constant-area nozzle. As a result, the net thrust obtained with the variable-area nozzle at an altitude of 25,000 feet, a flight Mach number of 0.53, and a turbine-outlet temperature of 1600° R was 8 percent lower than that obtained with the constant-area nozzle. At the same flight conditions and a net thrust of 1200 pounds, the specific fuel consumption was 8 percent higher with the variable-area nozzle than with the constant-area nozzle. With the results corrected to a nozzle efficiency of 100 percent, approximately the same thrust and specific fuel consumption were obtained at limiting engine conditions for the variable- and constant-area nozzles. Reducing the thrust by decreasing the engine speed with the constant-area nozzle or by increasing the nozzle area with the variable-area nozzle resulted in about the same specific fuel consumption.

At an altitude of 25,000 feet and a flight Mach number of 0.53, a 33-percent increase in nozzle area decreased the thrust about 47 percent. An equal thrust reduction with the constant-area nozzle, required an estimated reduction in engine speed from 12,350 to 10,500 rpm.

## INTRODUCTION

Because of the degree of thrust control that can be exercised at constant rotational speed with an engine equipped with a

variable-area exhaust nozzle, the performance characteristics of such an engine configuration are of great interest. Several operational problems would be relieved by regulating the thrust with a variable-area exhaust nozzle instead of changing the engine speed. One problem is the time required to change engine thrust. Because of the relatively high inertia of the rotor, considerable time is needed to accelerate or decelerate the engine. With a variable-area nozzle, however, rapid changes in thrust can be effected by varying the nozzle area. Another problem that might be alleviated is combustion blow-out, which is often encountered at reduced thrusts obtained at low engine speeds with a constant-area nozzle. With a variable-area nozzle, reduced thrusts can be obtained at high engine speeds by opening the exhaust nozzle.

An investigation of constant- and variable-area exhaust nozzles on a turbojet engine was made in the NACA Cleveland altitude wind tunnel during July 1947. Engine performance with the two nozzles was obtained for a wide range of flight conditions. A comparison of engine performance with each type of exhaust nozzle was then made on the basis of net thrust and net thrust specific fuel consumption. An analysis of the experimental results and a tabulation of the basic performance data are presented.

## ENGINE AND INSTALLATION

An early experimental Westinghouse 24C turbojet engine mounted in a wing nacelle was installed in the altitude-wind-tunnel test section (fig. 1). The engine consists of an 11-stage axial-flow compressor, an annular-type combustion chamber, and a two-stage turbine. For the first part of the investigation, the engine was equipped with an exhaust nozzle having a constant area of 1.187 square feet. This nozzle area was so selected that a turbine-outlet temperature of 1600° R would be obtained at rated engine speed and sealevel static conditions. For the second part of the investigation, the engine was equipped with a variable-area exhaust nozzle with which the projected-outlet area could be varied from 1.017 to 1.885 square feet. The variable-area nozzle was the clam-shell type, with pivot points at the top and the bottom of the tail pipe (fig. 2). A movable motor-driven yoke was used to change the nozzle area. Flexible steel sealing strips were installed on the front of the movable lip to minimize gas leakage (fig. 3). Detailed temperature and pressure surveys were obtained at six measuring stations in the engine, as shown in figure 4.

Dry refrigerated air was supplied to the engine through a duct from the tunnel make-up air system (fig. 1). The pressure and the 912

temperature at the compressor inlet (based on 100-percent rampressure recovery) were maintained at values corresponding to flight conditions in NACA standard atmosphere and the static pressure in the tunnel test section was maintained at the desired altitude value.

Engine thrust was obtained from measurements made with the tunnel balance scales. Engine air flow was calculated from values of pressure and temperature measured in the engine inlet duct (fig. 4, station 1).

## PROCEDURE

The performance of an axial-flow turbojet engine was obtained in the altitude wind tunnel for the following simulated flight conditions:

Altitude (ft)	Flight Mach number
5,000	0.12
15,000	.53
25,000	.12
25,000	.25
25,000	.53
25,000	.73
25,000	.86
25,000	.94
. 35,000	.52
45,000	.52

With the constant-area exhaust nozzle, the engine was operated over a wide range of engine speeds. With the variable-area exhaust nozzle, data were obtained at engine speeds of 11,000, 12,000, and 12,500 rpm (rated engine speed) at four exhaust-nozzle-outlet areas for each engine speed.

The symbols and equations used to calculate the results are given in the appendix.

## RESULTS AND DISCUSSION

In order to compare the engine performance with the two general types of nozzle, it is necessary to evaluate the effect of the nozzle losses. Experimental constant- and variable-area nozzle

efficiencies presented in figure 5 for several flight conditions and engine speeds show that the variable-area nozzle used in this investigation was less efficient than the constant-area nozzle. Exhaust-nozzle efficiency, which is defined as the ratio of the measured jet thrust to the jet thrust obtainable with no tail-pipe or nozzle losses, was calculated by means of equation (3) (appendix). The efficiency with the constant-area nozzle was about 95 percent for all flight conditions and engine speeds, whereas the efficiency with the variable-area nozzle varied from 87 to 93.5 percent. The losses obtained with the variable-area nozzle are attributed to gas deflection and turbulence at the nozzle outlet, together with leakage through the nozzle seals.

The engine performance with the constant- and variable-area exhaust nozzles has been compared on the basis of 100-percent efficiency for both nozzles and on the basis of the nozzle efficiencies actually obtained.

## Performance with 100-Percent Exhaust-Nozzle Efficiency

The variation of net thrust with turbine-outlet temperature and the variation of net thrust specific fuel consumption with net thrust are presented in figure 6 for constant- and variable-area exhaust nozzles (data corrected to nozzle efficiencies of 100 percent). Data are presented for several flight conditions at various engine speeds with the constant-area nozzle and at four nozzle areas for each of the three engine speeds with the variable-area nozzle. On the basis of equal exhaust-nozzle efficiency, about the same thrust and specific fuel consumption were obtained at corresponding engine speeds and turbine-outlet temperatures for both variable- and constant-area nozzles. Any slight differences at the same engine speed are due to experimental inaccuracies in the data.

At a given turbine-outlet temperature, increasing the engine speed with the variable-area nozzle sometimes decreased the net thrust (fig. 6(a)). A curve showing the variation of net thrust with turbine-outlet temperature does not, however, take account of the important parameter of exhaust-nozzle area. For example, at 12,000 rpm and a turbine-outlet temperature of 1122° R, the air flow was 28.26 pounds per second at a nozzle area of 1.487 square feet (table I, run 55; uncorrected values). At 12,500 rpm and at a turbine-outlet temperature of 1127° R, although the air flow did increase slightly to 28.60 pounds per second, the nozzle area was increased to 1.610 square feet (table I, run 59).

At an altitude of 25,000 feet, a flight Mach number of approximately 0.53, and a constant engine speed of 12,500 rpm, increasing the nozzle area from 1.211 to 1.610 square feet (33 percent) decreased the net thrust from 1378 to 738 pounds (46 percent). (See table I, runs 62 and 59.) In order to produce the same thrust decrease with the constant-area nozzle, an estimated reduction in engine speed from 12,350 to 10,500 rpm would be required. (See fig. 6(a).)

Effect of flight Mach number. - The effect of flight Mach number on net thrust and specific fuel consumption (fig. 7) for the variable- and constant-area exhaust nozzles, assuming 100-percent nozzle efficiency, was obtained by cross-plotting curves such as those presented in figure 6. It is a characteristic of this engine that an increase in flight Mach number reduced the turbine-outlet temperature obtained at any engine speed, whereas an increase in altitude at a given flight Mach number raised the turbine-outlet temperature. At high altitudes and low flight speeds, it was therefore impossible to obtain rated engine speed without exceeding the safe temperature limits of the engine. From a preliminary investigation of the constant-area nozzle at a flight Mach number of 0.25 and an altitude of 25,000 feet, a maximum turbine-outlet temperature of 1600° R was obtained at an engine speed of 12,080 rpm; at a flight Mach number of 0.94, a turbine-outlet temperature of 1570° R was obtained at 12,500 rpm. Consequently, at flight Mach numbers less than 0.80, the engine was limited by a turbine-outlet temperature of 1600° R (temperature obtained with the constant-area nozzle at sea-level static conditions) and at Mach numbers greater than 0.80, by an engine speed of 12,500 ppm. Because limiting temperatures could be maintained at rated engine speed for all flight Mach numbers with the variable-area nozzle, slight gains in thrust over that obtained with the constant-area nozzle are available at most Mach numbers. At a Mach number of about 0.80, at which limiting turbine-outlet temperature and rated engine speed could be obtained for the constant-area nozzle as well as the variable-area nozzle. the thrusts with both nozzles were approximately the same (fig. 7). The net thrust specific fuel consumptions obtained with the constantand variable-area nozzles at maximum engine conditions were approximately equal for all flight speeds.

The variation of net thrust specific fuel consumption with flight Mach number is shown in figure 8 for three reduced values of net thrust. Thrust with the variable-area nozzle was reduced by increasing the nozzle area. Although most data with this nozzle were obtained at rated engine speed, in a few cases an engine speed of 12,000 rpm was used because a slightly lower specific fuel consumption was obtainable at the same thrust. At thrust values of

겂

80 and 65 percent of the maximum available thrust, the specific fuel consumption was approximately the same for the constant- and variable-area nozzles at all flight speeds when compared at 100-percent nozzle efficiency. At 50 percent of the maximum available thrust, however, slightly lower specific fuel consumptions were obtained with the variable-area nozzle.

Effect of altitude. - The variation of net thrust and specific fuel consumption with altitude for the constant- and variable-area exhaust nozzles with an assumed efficiency of 100 percent (fig. 9) was obtained from cross plots of curves similar to those shown in figure 6. Because the turbine-outlet temperature increased as the altitude was raised at a given flight Mach number, it was necessary to reduce the rotational speed as the altitude was increased in order to operate within the temperature limits with the constant-area nozzle. With the variable-area nozzle, however, rated speed and limiting turbine-outlet temperatures were maintained at high altitudes by increasing the nozzle area.

At an altitude of 15,000 feet and a flight Mach number of 0.53, a turbine-outlet temperature of about 1600° R was obtained at an engine speed of 12,500 rpm with the constant-area exhaust nozzle; whereas at 45,000 feet and the same flight Mach number, the limiting turbine-outlet temperature (1600° R) was obtained at 11,150 rpm. For altitudes from 15,000 to 25,000 feet, the net thrust and the specific fuel consumption obtained with both exhaust nozzles operating at 100-percent efficiency were approximately the same. The slight disagreement at low altitudes is attributed to experimental inaccuracies in the data. At altitudes above approximately 30,000 feet, however, at which the engine speed with the constant-area nozzle was considerably reduced, higher thrusts and slightly lower specific fuel consumptions were obtained with the variable-area nozzle (fig. 9).

# Performance with Actual Exhaust-Nozzle Efficiencies

Performance data obtained with the exhaust-nozzle efficiencies indicated in figure 5 are shown in figure 10 for the variable- and constant-area nozzles at several flight conditions. With the efficiencies shown in figure 5, higher thrusts and lower specific fuel consumptions were more often obtained with the constant-area nozzle than with the variable-area nozzle (fig. 10).

Exhaust-nozzle efficiencies and the effect they can produce on net thrust and specific fuel consumption are shown in figure 11 for an altitude of 25,000 feet and a flight Mach number of 0.53. An

efficiency of about 95 percent is indicated for the constant-area nozzle, whereas an efficiency of about 91 percent is shown for the variable-area nozzle at rated engine speed. The nozzle losses have a larger percentage effect on net thrust and specific fuel consumption based on net thrust than they do on the nozzle efficiency, which is based on jet thrust. For nozzle efficiencies of 100 percent, the net thrust with the constant-area nozzle was 2 percent higher than with the variable-area nozzle at 1600° R. For the actual nozzle efficiencies, the net thrust with the constant-area nozzle was about 8 percent higher than with the variable-area nozzle at 1600° R. At a net thrust of 1200 pounds, the specific fuel consumptions with both nozzles were about the same for nozzle efficiencies of 100 percent. With the actual nozzle efficiencies at the same thrust, however, the specific fuel consumption with the variable-area nozzle was 8 percent higher than with the constant-area nozzle.

Effect of flight Mach number. - From a cross plot of curves similar to those shown in figure 10, the variation of measured net thrust and specific fuel consumption with flight Mach number was obtained (fig. 12). For all flight Mach numbers investigated at an altitude of 25,000 feet, higher thrusts and lower specific fuel consumptions were obtained with the constant-area nozzle than with the variable-area nozzle. The relatively low thrust and high specific fuel consumption obtained with the variable-area nozzle is a direct effect of the nozzle losses. The variation of specific fuel consumption with flight Mach number for both types of nozzle is shown in figure 13 for three reduced values of net thrust. Thrust with the variable-area nozzle was reduced by increasing the nozzle area. Although most of the data with this nozzle are for rated engine speed, in a few cases an engine speed of 12,000 rpm was used because a slightly lower specific fuel consumption was obtainable at the same thrust. For practically all flight Mach numbers at the three thrust values shown, the specific fuel consumption obtained with the constant-area nozzle was lower than that obtained with the variable-area nozzle.

An advantage of the variable-area exhaust nozzle is the degree of thrust variation that can be obtained without changing the rotational speed of the engine. The variation of net thrust with exhaust-nozzle area for various flight Mach numbers at 25,000 feet is presented in figure 14. For the range of data investigated, the percentage decrease in thrust that was obtained for a given increase in nozzle area is independent of flight Mach number. The data shown for flight Mach numbers of 0.12 and 0.25 indicate that little change in thrust can be obtained by further increases in nozzle area.

Effect of altitude. - The variation of net thrust and specific fuel consumption with altitude (fig. 15) was obtained from cross plots of curves similar to those shown in figure 10. For altitudes from 15,000 to 25,000 feet, the thrust obtained with the constantarea nozzle was considerably higher than that obtained with the variable-area nozzle. As the altitude was increased, however, the engine speed with the constant-area nozzle was reduced in order to stay within the engine temperature limits. Thus at altitudes above 37,000 feet, a higher thrust was obtained with the variable-area nozzle than with the constant-area nozzle (fig. 15). The specific fuel consumption at all altitudes investigated was higher with the variable-area nozzle than with the constant-area nozzle.

The variation of net thrust with exhaust-nozzle area for various altitudes at a flight Mach number of approximately 0.53 is presented in figure 16. For a given increase in nozzle area, the decrease in thrust that was obtained was essentially independent of altitude.

#### SUMMARY OF RESULTS

The following results were obtained from an altitude-windtunnel investigation of turbojet engine performance with constantand variable-area exhaust nozzles for a wide range of altitudes and flight Mach numbers. The engine has an ll-stage axial-flow compressor and a two-stage turbine.

- 1. The efficiency of the variable-area exhaust nozzle was 1.5 to 8 percent lower than that of the constant-area nozzle. As a result, the net thrust with the variable-area nozzle at an altitude of 25,000 feet, a flight Mach number of 0.53, and a turbine-outlet temperature of 1600° R was 8 percent lower than that obtained with the constant-area nozzle. At the same flight conditions and a net thrust of 1200 pounds, the specific fuel consumption was 8 percent higher with the variable-area nozzle than with the constant-area nozzle.
- 2. With the results corrected to a nozzle efficiency of 100 percent, approximately the same net thrust and specific fuel consumption was obtained at limiting engine conditions for the variable- and constant-area nozzles. Reducing the thrust by decreasing the engine speed with the constant-area nozzle or by increasing the nozzle area with the variable-area nozzle resulted in about the same specific fuel consumption.

3. At an altitude of 25,000 feet and a flight Mach number of 0.53, increasing the nozzle area 33 percent decreased the thrust about 46 percent. An equal thrust reduction with the constant-area nozzle required an estimated reduction in engine speed from 12,350 to about 10,500 rpm.

## METHODS OF CALCULATION

## Symbols

- A cross-sectional area, sq ft
- Fj jet thrust, 1b
- Fj' jet thrust assuming no losses in tail pipe or nozzle, lb
- F<sub>n</sub> net thrust, lb
- Fn' net thrust assuming no losses in tail pipe or nozzle, lb
- g acceleration due to gravity, 32.2 ft/sec2
- P total pressure, lb/sq ft absolute
- p static pressure, lb/sq ft absolute
- R gas constant, 53.3 ft-lb/(lb)(OR)
- T total temperature, OR
- Ti indicated temperature, OR
- t static temperature, OR
- V velocity, ft/sec
- Wa air flow, lb/sec
- We fuel flow, lb/hr
- Wg gas flow, lb/sec
- $W_f/F_n$  net thrust specific fuel consumption, lb/(hr)(lb thrust)
- a thermocouple recovery factor, 0.85
- γ ratio of specific heats
- η exhaust-nozzle efficiency, ratio of measured jet thrust to jet thrust obtainable with no tail-pipe or nozzle losses

## Subscripts:

- O free-stream conditions
- 2 compressor inlet
- 5 turbine outlet

## Temperature

Total temperature was calculated from

$$T = \frac{T_1\left(\frac{P}{p}\right)^{\frac{\gamma-1}{\gamma}}}{1 + \alpha\left[\left(\frac{P}{p}\right)^{\frac{\gamma-1}{\gamma}} - 1\right]}$$
(1)

## Air Flow

The engine air flow was obtained from

$$W_{a} = p_{2}A_{2} \sqrt{\frac{2\gamma g}{(\gamma-1)RT_{2}} \left(\frac{p_{2}}{p_{2}}\right)^{\frac{\gamma-1}{\gamma}} \left[\left(\frac{p_{2}}{p_{2}}\right)^{\frac{\gamma-1}{\gamma}} - 1\right]}$$
(2)

#### Net Thrust

The free-stream momentum of the engine air flow was subtracted from the jet thrust, as measured by the tunnel balance scales, to obtain the net thrust

$$\mathbf{F_n} = \mathbf{F_j} - \frac{\mathbf{W_a V_0}}{\mathbf{g}}$$

The ideal jet thrust that was required to determine the exhaustnozzle efficiency was obtained from the engine mass flow, measurements at the turbine outlet, and the ambient static pressure

$$\mathbf{F_{j'}} = \frac{\mathbf{W_g}}{\mathbf{g}} \sqrt{\frac{2\gamma}{\gamma - 1}} \operatorname{Rg} \mathbf{T_5} \left[ 1 - \left(\frac{\mathbf{p_0}}{\mathbf{P_5}}\right)^{\frac{\gamma - 1}{\gamma}} \right]$$
 (3)

The exhaust-nozzle efficiency was defined as

$$\eta = \frac{\mathbf{F}_{\mathbf{j}}}{\mathbf{F}_{\mathbf{j}}},$$
